

Ho-hum. Another terrifying climate study, this one about melting ice in the Antarctic

By John Eidson | April 4, 2016

Cleverly disguised as journalists, progressive propagandists in the media are leaving no stone unturned at helping the climate fear industry hype a dire new study alleging that Antarctica is melting “much faster than anticipated,” so much faster that it threatens a catastrophic sea level rise, not centuries from now, but in mere decades, maybe even *this* decade.

You can relax. The study’s apocalyptic forecast is not based on actual scientific observations. No, its enormously uncertain finding is based on **speculative computer models**. That would be the same kind of speculative modeling that has produced thousands of terrifying climate predictions dating to the 1980s, not a single one of which has even come close to happening.

Why has the climate fear industry been 100% perfect at making wildly inaccurate predictions? Partly because government-funded climate scientists with families to feed are not stupid. If they fear their job’s on the line, that’s all the incentive they need to rationalize coming up with conclusions that won’t anger their government paymasters.

Research that arrives at a politically-approved outcome—i.e., research that ensures you get to keep your job—is known in computer lingo as garbage in, garbage out. It’s also known as [cooking the books](#). Btw, if you doubt government would fire scientists on its payroll simply for expressing a dissenting opinion, [dream on](#).

Finally, if you’d like to understand the “science” behind man-made global warming theory, the illustration at the top will teach you all you need to know.
